and

Angelos D. Heliotis
MIT Department of Ocean Engineering

Introduction:

This report describes the research conducted at MIT on bulbous bow retrofits applied to a Canadian trawler 50 meters in length. This is the third vessel in a series of three trawler hulls included in a larger study. The results from the other trawlers are presented in a recent Master's Thesis by Heliotis(1).

The most significant part of the thesis and this report is the ship model towing tank results. Experimental data and analyses are supplemented by results from the MIT 5-D Ship Motions Program(2) and results from a resistance regression model by Holtrop(3) as implemented on computer by Sedat(4).

The lines drawing of the 50 meter trawler(5) was provided by the Canadian Department of Fisheries and Oceans together with information on the propulsion and operation of the vessel in its present fishery. A 4.5' model of the hull was constructed and a series of 12 bulbous bow retrofits were prepared.

Calm water model resistance tests were conducted on the bare hull and then with each retrofitted bulb. All tests were done at constant draft, i.e., the bulb configurations were of heavier displacement than the original hull. The calm water results were compared and a "best" bulb was selected for seakeeping tests. The bare and bulbous models were tested in regular waves over a range of wave lengths at both steaming and trawling speeds. Pitch, heave, bow accelerations, and resistance were measured. These results are compared with the 5-D program predictions.

All bulbs were fitted to the maximum limits of the forward draft and a regression model was used to explore the effects of varying the vertical bulb location. Propeller calculations were then used to predict the effect on BHP requirements based on the performance of the best bulb.

Model Construction:

The available lines drawing included only the water lines and buttock lines. From these a section drawing was prepared as shown in Figure 1.

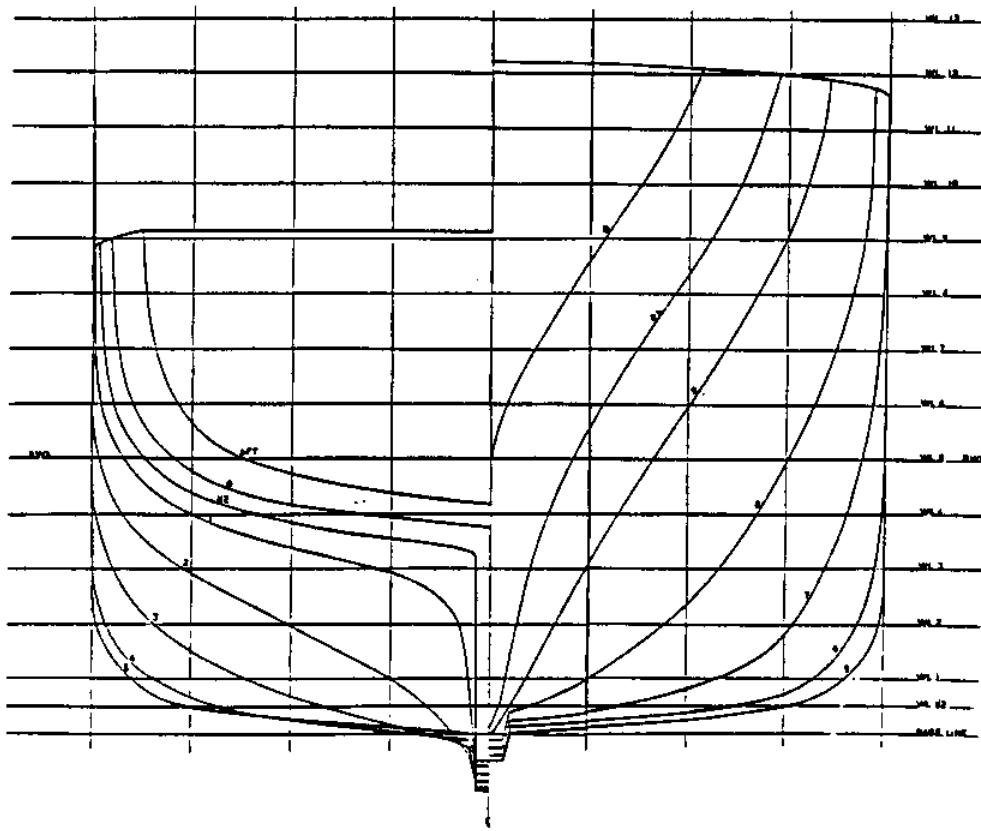

Figure 1. Section drawing of the 50m freshfish stern trawler

These drawings were photographically reduced to yield an image of 4.5' overall length. Sea Tech Inc., of Hingham, Massachusetts was contracted to construct the model from clear pine using these reduced drawings. The hull was laminated from planks planed to the thickness of the waterline spacing. To allow for ballasting, the hull is hollow but with a minimum wall thickness of 1.0 inches. A strip of 0.030" walnut veneer was rabbeted-in along the design waterline. After sanding to specified tolerances and fairness, the hull was finished with multiple coats of marine varnish. The scale ratio of the model was 35.62 to 1.

The bulb retrofits studied were cylindrical with hemispherical caps. This geometry was selected due to its potential economy of full-size fabrication and reports of some success with this type of bulb on the U.S. West Coast(6). The parameters varied were diameter and length. All bulbs were positioned with their lower edge even with the intersection of the forward perpendicular and an extension of the bottom of the keel.

Three bulb diameters were used to cover a range of possible sizes from 10 to 30 percent of the midship section area. The same bulb retrofits used during the earlier trawler experiments were used on this model. These were 2", 3.5", and 4.5" in diameter and for this hull the actual bulb percentages were 9, 18.5, and 30.3, respectively. In most cases throughout this report, they are referred to simply as 10, 20, and 30 percent bulbs.

The hemispherical caps were machined on a numerically controlled lathe from PVC round bar. Transition pieces were constructed from PVC tubing to attach the caps to the hull. Lengthening rings of 0.5, 1.0, and 1.5 diameters were prepared to allow for variation of bulb length. Each retrofit component was designed to be a press-fit with its neighbor. The transition pieces were accurately fitted to the hull and a thin application of silicone caulk at each joint was all that was needed to keep the bulbs in place and watertight. A description of each bulb is presented in Table 1. Figures 2 through 5 are photos of the retrofitted model during the testing.

Bulb Description	Percent of A	Diameter (feet)	Length Fwd. of Stem(ft)	Submergence (feet)
10%	9.1	5.94	4.8	-7.0
10% - 0.5D	9.1	5.94	7.8	-7.0
10% - 1.0D	9.1	5.94	10.7	-7.0
10% - 1.5D	9.1	5.94	13.7	-7.0
20%	18.5	10.40	5.9	-2.5
20% - 0.5D	18.5	10.40	11.1	-2.5
20% - 1.0D	18.5	10.40	16.3	-2.5
20% - 1.5D	18.5	10.40	21.5	-2.5
30%	30.5	13.37	6.7	+0.4
30% - 0.5D	30.5	13.37	13.4	+0.4
30% - 1.0D	30.5	13.37	20.1	+0.4
30% - 1.5D	30.5	13.37	26.7	+0.4

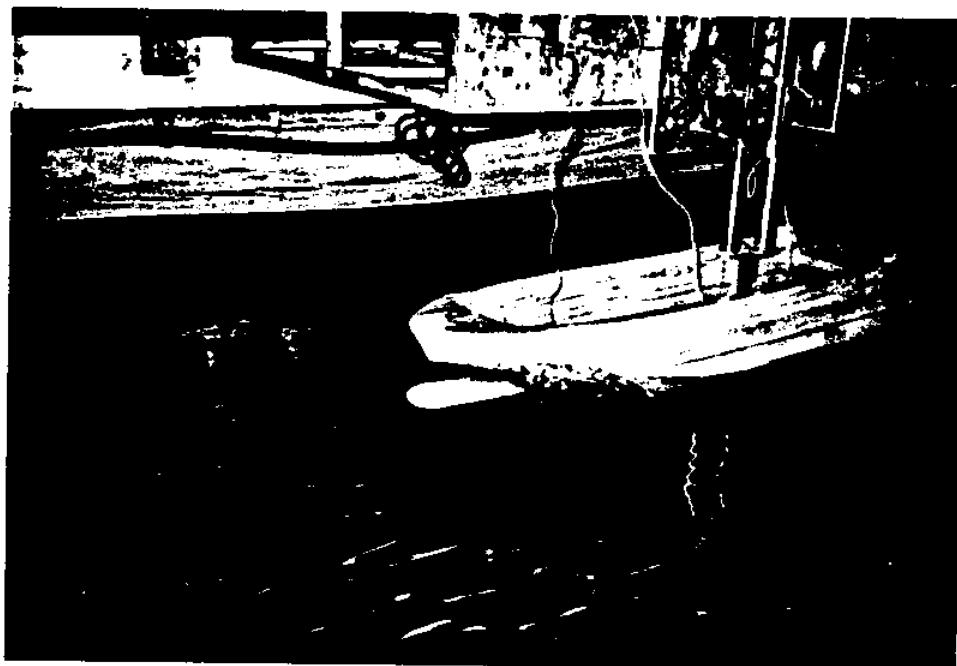

Figure 5. The 20% - 0.5D bulb during seakeeping tests.

Test Facility:

The MIT Ship Model Towing Tank is 108' long, 8' 7" wide, with a normal water depth of 4' (7). The towing carriage is instrumented for resistance and motions measurements. One end of the tank is fitted with a wave generator while the other end has a wave absorbing "beach". Regular waves and various sea spectra can be developed.

Test Procedure:

To insure a proper transition from laminar to turbulent flow, a row of turbulence stimulators was attached to the hull 4% of the LWL behind the stem. These were comprised of 0.125" diameter by 0.062" long studs spaced 0.25" apart. When the bulbs were attached, the row of studs were continued in a vertical line around the transition piece.

The base hull was floated in the tow tank and ballasted to its design water line. Lead billets were used and fixed in place with clay. The correct displacement was then verified by weighing the ballasted model.

The towing carriage force block was attached to the inside of the hull at the center of floatation, on the centerline, and in a vertical position such that the force applied to the model would be approximately in line with the location of the propeller shaft. The force block is designed to pivot about the pitch axis and is attached to air-bearing heave rods to allow for vertical motions. The model is restrained from roll, sway, yaw, and surge relative to the carriage.

The model was towed over a range of ship speeds from 3 to 15 knots. The order of speed selection was randomized and five minutes elapsed before commencing the next run or until all waves from the previous run dissipated. The actual speeds of each run are tabularized in Appendix A.

The procedure was repeated for each bulb retrofit. Ballast was added to the bow to counteract the buoyancy of the bulb. In some cases, the overall ballast arrangement had to be adjusted due to the forward location of the bulbs.

As noted in Table 1, the top surface of the 30% bulb was above the still waterline due to its size relative to the forward draft. At all towing speeds this bulb became submerged.

The seakeeping tests were done in a similar manner except that the placement of the ballast in the model was done to yield a longitudinal radius of gyration of 0.25 of the model length. Runs were made at ship speeds of 1.5 knots and 3.0 knots to represent reported steaming and trawling conditions. Wave lengths from 0.7 to 3.0 times LWL were generated. Wave heights were maintained at a constant 5% of the LWL.

Since the pitch and heave response of a trawler is clearly affected by the presence of the trawl gear during trawling, this effect was simulated during the tank tests. A parachute-type drogue with appropriate drag characteristics was towed from a point on the transom centerline at the main deck. This was kept submerged by a weight at the junction of the tow wire and the drogue. The weight was equivalent to the weight of two appropriately sized trawl doors and produced a vertical warp angle of approximately 20 degrees. The set-up is diagrammed in reference 1.

Pitch motions, heave motions, bow accelerations, and wave height were recorded during each run. The accelerometer was located on the O1 deck at station 10 1/2.

Calm Water Results:

The model drag at each calm-water speed is presented in the tables of Appendix 1 together with the nondimensionalized values and the scaled-up results. These results are presented graphically in Appendix 2 where comparisons among the various bulb lengths are included.

Figure 6 shows the effect of bulb size on EHP for speeds of 10, 11.5, and 13 knots. Attempts to interpolate between the discrete bulb sizes should be discouraged, however the advantage of larger bulbs at higher speeds is evident.

To demonstrate more clearly the importance of operating speed on optimum bulb selection, the EHP changes for the three bulb diameters are presented versus speed in Figure 7. This reveals that the 20% bulb offers an advantage over the range of speeds above 4 knots. The 10% bulb is superior to the 20% bulb at the lower speeds, however above 10 knots its effect is diminished, becoming a detriment above 11.5 knots. The 30% bulb is a clear detriment at lower speeds due to its large wetted surface but offers an advantage above 11.5 knots. Above 13 knots and beyond the range of the graph, the 30% bulb is most beneficial.

In Figures 6 and 7, the best length bulb for each diameter is used in the comparisons. It can be seen in Appendix 2 that the effect of length variations is more important with the 20 and 30 percent bulbs. We should recall however that the length increments are based on diameter and the actual length variations of these larger bulbs were quite extreme (see Table 1).

To better visualize the effects of length, the results of the four 20% bulbs are shown in Figure 8 in terms of EHP changes relative to the bare hull. From this it can be seen that the 0.5 D. ring presents the greatest potential over the speeds of interest. Only the shortest version offers no benefits over the speed range covered.

EFFECT OF BULB SIZE ON EHP

EFFECT OF BULB LENGTH ON EHP

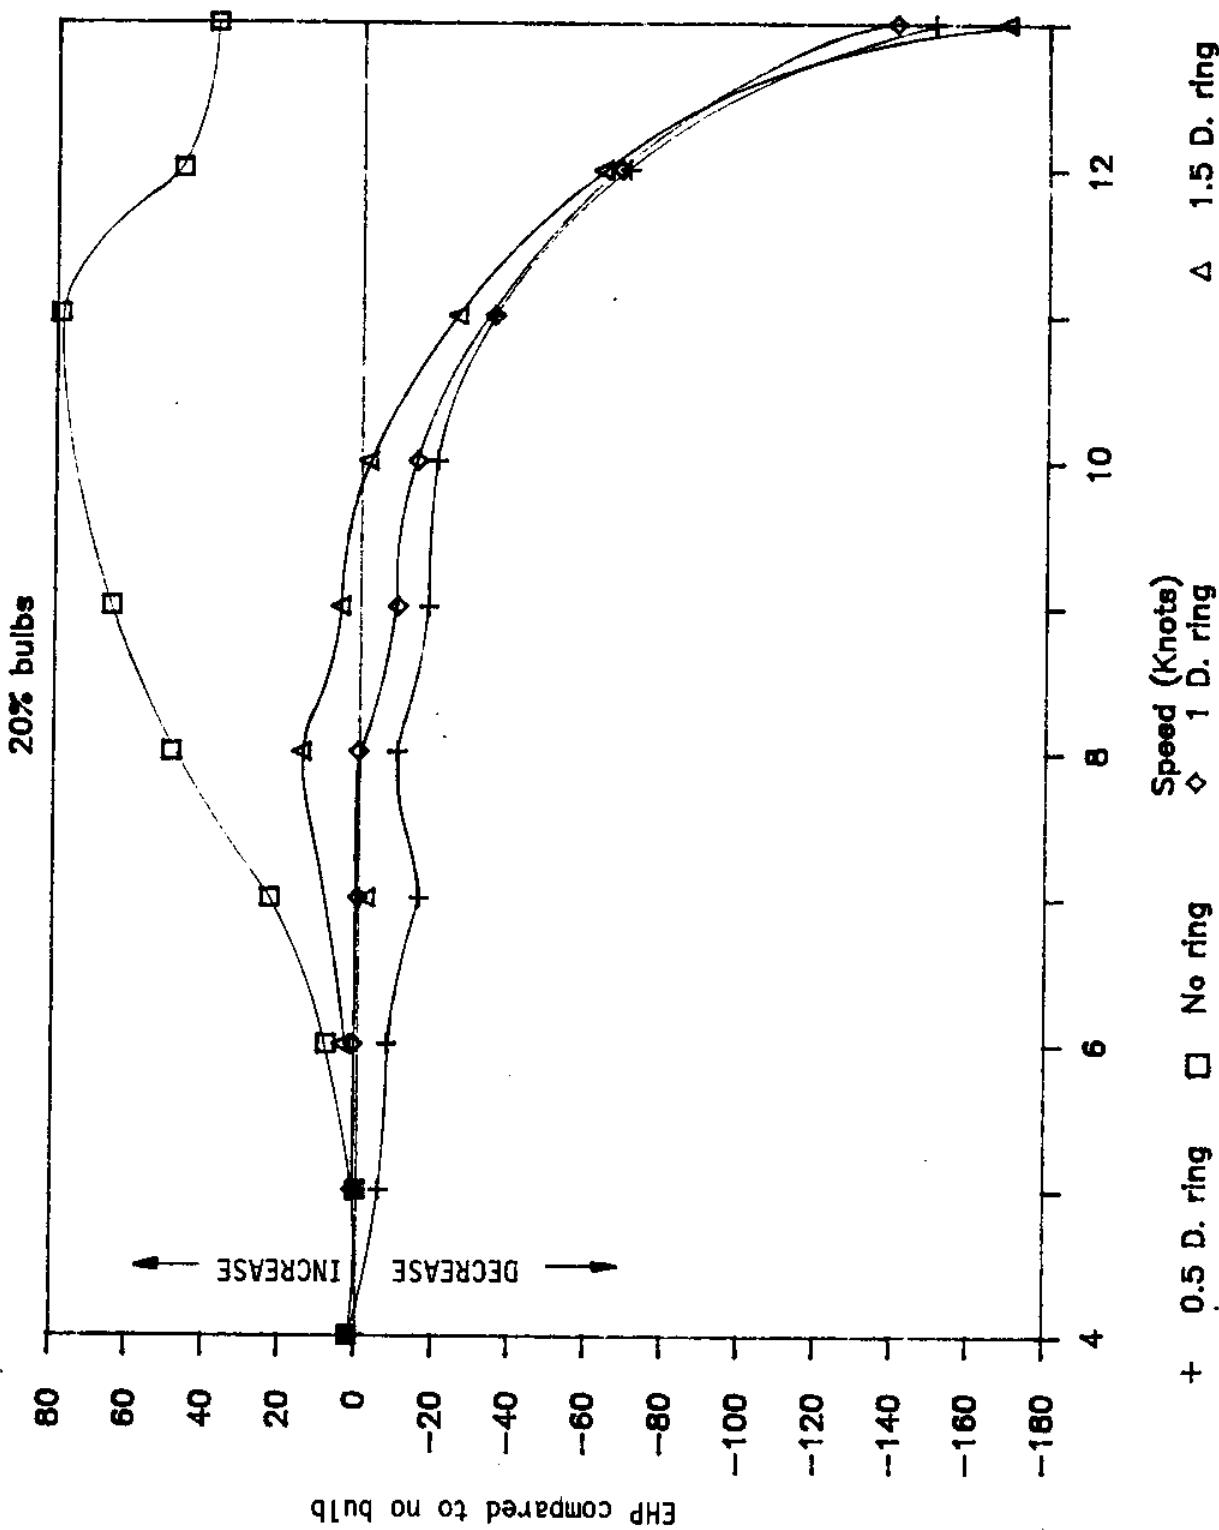

Figure 8

Regular wave Results:

From the recorded data the average pitch and acceleration responses were determined for each regular wave length. For the cruising speed, the non-dimensionalized pitch results are shown in Figure 9. Comparing the 20% bulb with the bare hull we can see the bulb's apparent effectiveness in reducing pitch at wave lengths less than two ship lengths. Above this point the bulb seems to be a disadvantage.

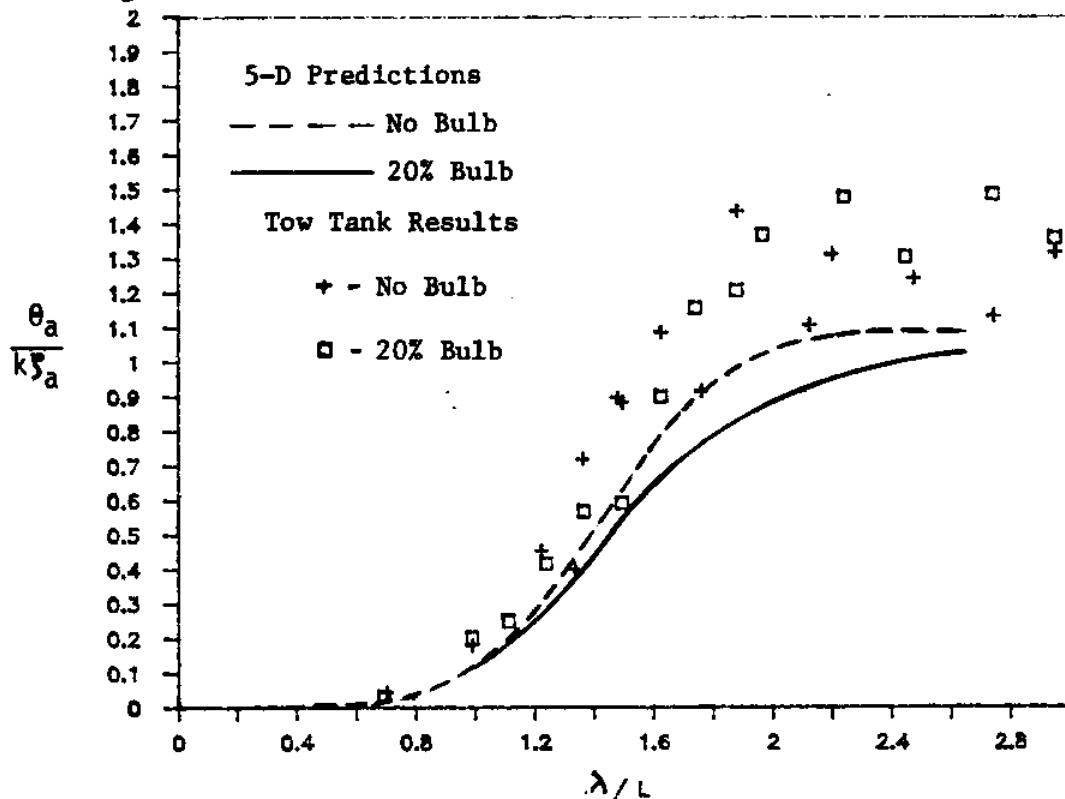

Figure 9. Pitch response at a cruising speed of 11.5 knots.

Figure 10 is a similar presentation of bow accelerations. The significance of the bulb is more evident since the higher frequencies associated with the shorter wave lengths are important with respect to accelerations and crew comfort.

As would be expected, the pitch response levels-off at the longer wave lengths as the vessel begins to simply follow the slope of the wave surface. The lower frequencies in this region cause the accelerations to diminish and little difference is found with the bulb.

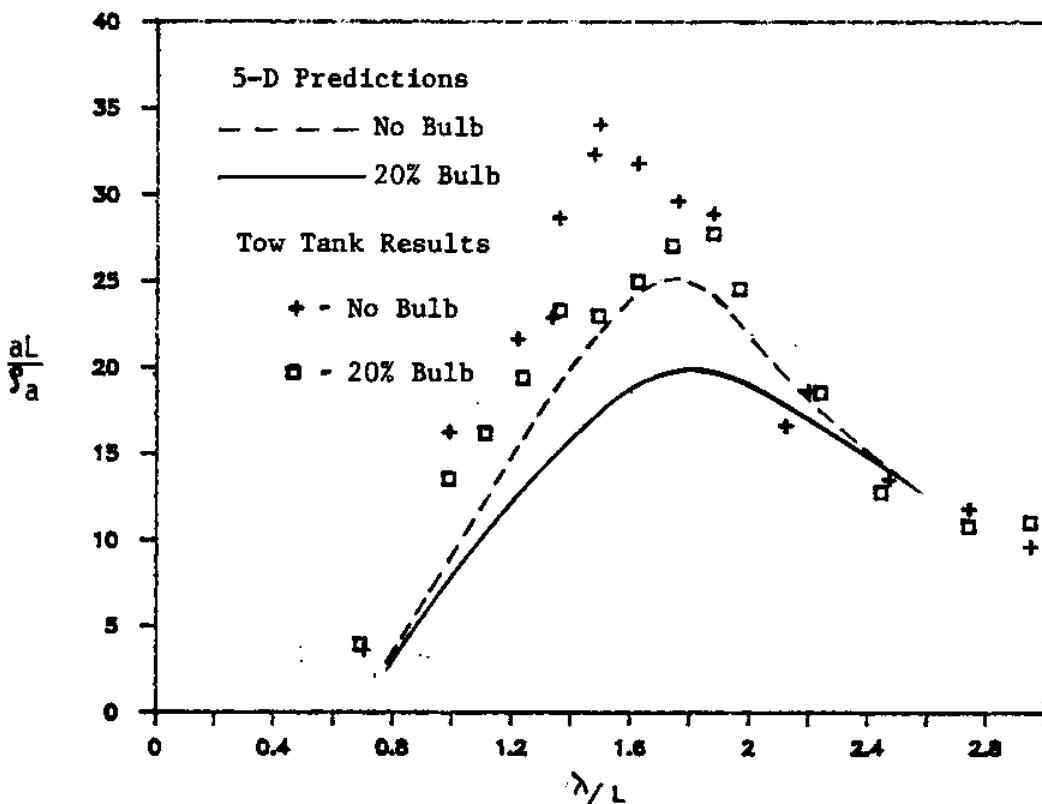

Figure 10. Vertical bow accelerations at 11.5 knots.

The results at a trawling speed of 3.0 knots are presented in Figures 11 and 12. Here the effect of the bulb, if any, is not evident. The presence of the trawl-simulating drogue causes the motions to become more complicated than would occur with the trawler alone. The frequent coincidence of bare and bulb data suggests an unusual system response which is not effected by minor changes in the hull form.

We are unaware of any previous experiments of this type other than those reported in the thesis by Heliotis(1). Trawl interaction with vessel motion is an area where research is obviously needed.

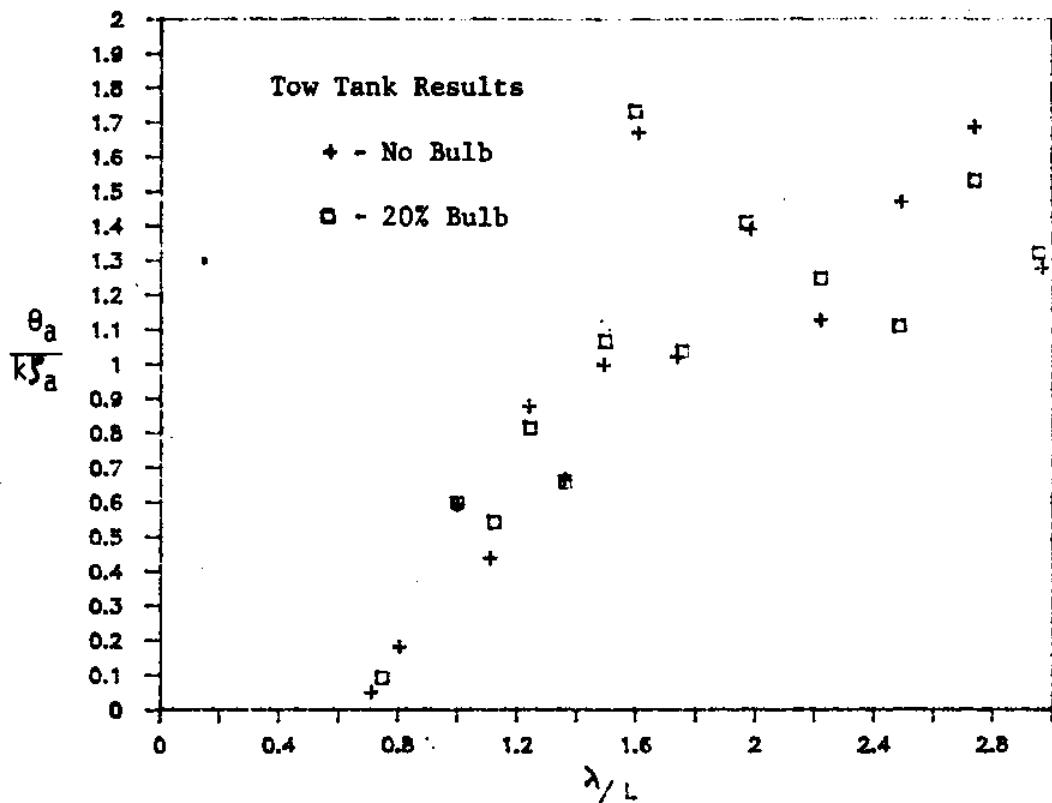

Figure 7. Pitch response at 3.0 knots with drogue.

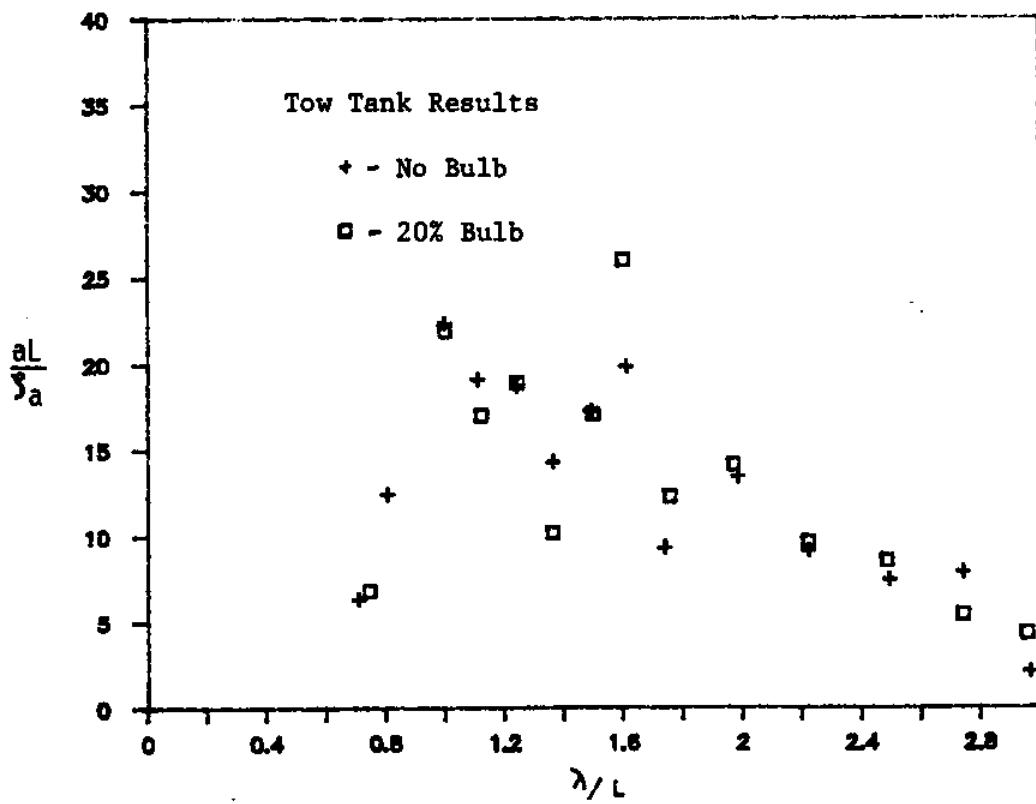

Figure 8. Vertical bow accelerations at 3.0 knots with drogue.

Added Resistance Results:

Vessel motions affect powering requirements therefore resistance measurements were taken during the seakeeping tests. The results are presented in Figures 13 and 14 in terms of non-dimensionalized added resistance σ_w , defined by:

$$\sigma_w = \frac{R - R_{\text{calm}}}{\rho g B^2 / L^3 a}$$

Figure 13 shows that in a seaway, the 20% bulb experiences more added resistance than the bare hull counterpart. However, since the results are based on the difference between the measured resistance and the corresponding calm-water resistance, the net effect is less important since the 20% bulb has less resistance to begin with.

At the trawling speed the results are uninterpretable due to the complex response caused by the drogue/vessel system. In this case, the resistance found while towing the drogue in calm water is used in the comparison.

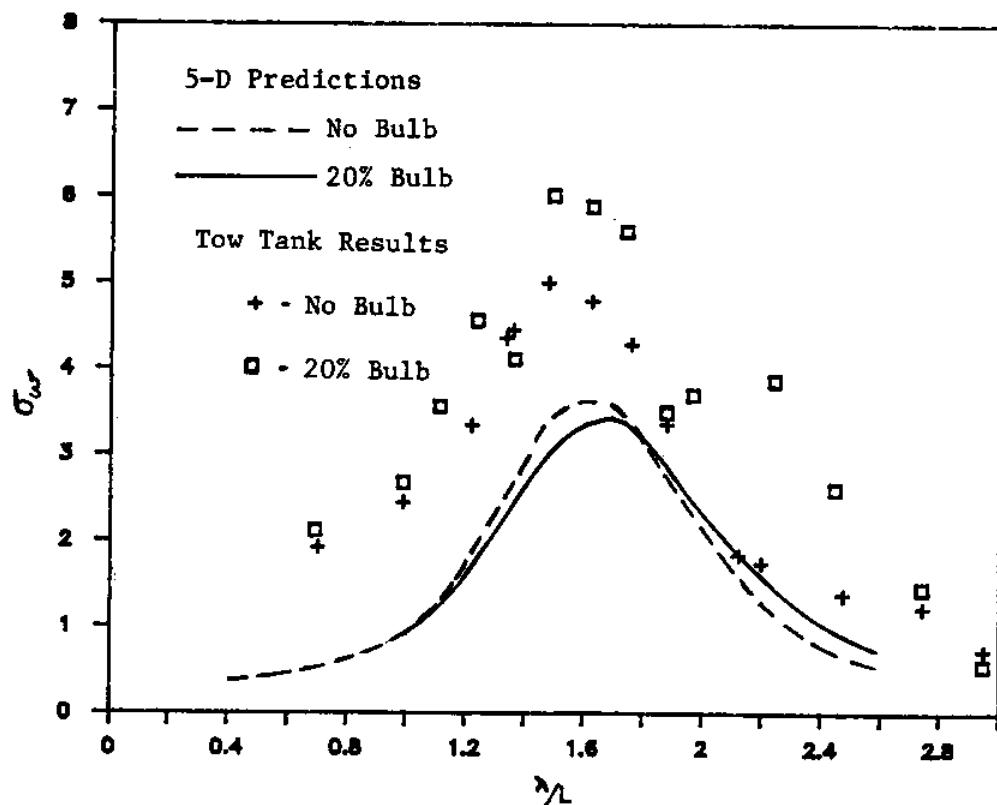

Figure 13. Added resistance at a cruising speed of 11.5 knots.

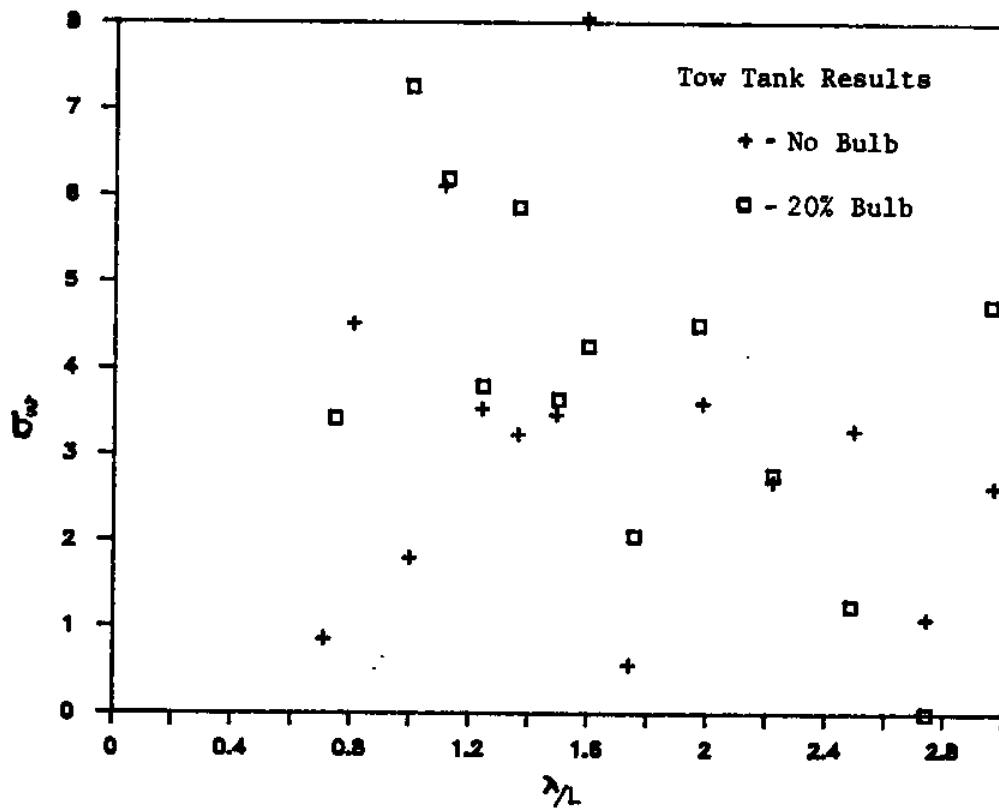

Figure 14. Added resistance at 3.0 knots with drogue.

5-D Motions Program Results:

The MIT 5-D Ship Motions Prediction Program(2) was run on the bare hull and the 20%-0.5D bulb over a range of regular waves comparable to the tow tank experiments. These runs were for the cruising speed only since the program is unable to include the effects of a towed object.

The results are plotted in Figures 9, 10, and 13 for comparison with the experimental data. The program results clearly show the pitch damping effects of the bulb retrofit. Reasonable agreement with the tow tank results are found, especially in the shorter wave lengths for pitch and the longer wave lengths for accelerations. There is some disagreement in results for added resistance in the vicinity of the peak.

The similar trends between the experimental and computer results are encouraging. The differences in actual response values could be due to the fact that the 5-D program is best suited for more slender ships than the one under consideration.

Effect of Bulb Height:

Exploring experimentally the effect of bulb height was beyond the scope of this research. To gain some insight into the possible advantage of vertical locations other than those tested, a regression model was used. The model is based on a compilation of test results from the Netherlands Ship Model Basin(3) and an implementation in PC BASIC was obtained from Webb Institute. The model includes bulb area and centroid height above the baseline as parameters. It is doubtful however, that it was intended for use on trawler-type hulls.

The results of a series of runs with and without bulbs are presented in Appendix 3. Most noticeable is the underestimation of the 50m trawler's resistance based on the hull description.

Comparing the bare hull with the 10% predictions at 11.5 knots, the relative benefits of the bulb forms are in remarkable agreement with our experimental results. Further, we might interpret that a slight improvement could be gained by moving this small bulb closer to the surface by two or three feet.

The predictions for the 20% bulb show little change from the bare hull values at 11 and 12 knots. At higher speeds the bulb is beneficial. Similarly, the 30% bulb is of little use except at these high speeds. Using 15 knot results as a guide, it seems that the 5.0' height used in the experiments is suitable. The 30% values suggest that our forward draft limitation was restrictive and dropping the bulb by two or three feet might be helpful.

Power Requirement Calculations:

The calm water reduction in EHP requirements with the 20% -.05D bulb at 11.5 knots is 52 horsepower as shown in Figure 3. From Appendix 2, the bare hull EHP at that speed is 600 horsepower. The net effect on shaft horsepower (SHP) is dependent on a variety of efficiencies and conditions which can be calculated or estimated. They are summarized in Table 2.

The SHP reduction of the retrofit bulb depends upon the operating regime of the engine. If the propeller turns are maintained at full RPM the propeller efficiency changes very little and the reduction remains at 10%. If a more moderate RPM is allowed the reduced resistance allows an improved propulsion efficiency and the net reduction in SHP of 13.3%.

Parameter	Bare Hull	With 20% - 0.5D Bulb

SHP	1074 1054	975 930

Table 2. Power Calculations.

Conclusions:

Our results indicate significant reductions in SHP requirements for the simple bulb designs we tested. It is also evident that if this vessel was operated at a speed/length ratio more typical of trawlers, the benefits would be much greater. For example, Figure 8 predicts EHP reductions of over 165 horsepower (17%) at 13 knots.

The simple shaped bulbs included in this study are crude compared to the carefully formed bulb commonly seen on merchant ships and naval vessels. We feel that the complication of fabricating the latter type is inconsistent with the construction practices used for most fishing vessels.

The calculations of SHP summarized in Table 2 are based on the information available. The wake fraction and thrust deduction were estimated from data related to ship hulls. In addition, the propeller efficiencies are based on B-Series data since the specifications of the nozzle were unavailable. Propeller B 4-85 was assumed.

In general, the reduced propeller thrust required for the retrofitted vessel at steaming speed should result in improved propulsive efficiency.

Since the resistance and SHP requirements are based on constant draft rather than constant displacement, the results presented here may be conservative. Increased payload due to the bulb's volume may be possible. Conversely, if stability conditions allow, the buoyancy of the bulb could be used to decrease the forward draft and allow further resistance reductions.
